Abstract
The efficiency of newly synthesized single site phase transfer catalyst has been studied with the help of kinetics of free radical polymerization of methyl and ethyl methacrylate (MMA and EMA). The radical polymerization was catalyzed with single site phase transfer catalyst, 2-benzoylethyldecyldimethylammonium bromide (BEDDAB) and initiated by water soluble potassium peroxydisulphate initiator in ethyl acetate / water biphase media under inert condition at constant temperature 60±1ºC. The prepared phase transfer catalyst has been characterized by FT-IR, 1H-NMR and 13C-NMR as well as C, H and N elemental analysis. The order of the reaction with respect to monomer, initiator, phase transfer catalyst (PTC) and temperature was ascertained. A suitable kinetic mechanism has been proposed as per the experimental conditions. Molecular weight of the polymethyl methacrylate (PMMA) as well as polyethylmethacrylate (PEMA) which have been polymerized using phase transfer catalyst was evaluated using GPC technique.

Keywords: Single site phase transfer catalyst; 2-Benzoylethyldecyldimethylammonium bromide; Kinetic mechanism; Radical polymerization.

Introduction
Rapid industrialization and revolution has focused significant attention on green chemistry. Among the new developments in the organic synthesis towards green technology, reactions involving phase transfer catalyst has become a versatile technique because of its mild reaction conditions, large conversion and product selectivity [1-3]. Though the reaction between hydrophilic and lipophilic reactants can be facilitated by appropriate aprotic solvent, the separation of solvent from the reaction mixture and the cost has established the phase transfer catalyst as a power tool in bringing plausible reaction between two mutually immiscible phases. The first published biphasic method for the generation of dichlorocarbene by Makosza [4] has triggered and propelled the application of phase transfer catalyst in organic synthesis. Hence it has become a fascinating area of research. Researchers studied the success of single site phase transfer catalyst especially in free radical vinyl monomers involving aqueous-organic biphase media [5-17]. These studies provoked us to check the efficiency of a newly synthesized single-site phase transfer catalyst by polymerizing MMA and EMA and its competency has been analyzed by kinetic study using water soluble potassium peroxydisulphate (PDS) initiator.

Experimental Details
Materials and Methods
The monomers methyl methacrylate and ethyl methacrylate (Merck, Mumbai) were subjected to reduced pressure distillation before use. The water soluble initiator, potassium peroxydisulphate (SRL, Mumbai) was used as such. Methanol (SRL, Mumbai) was distilled over a water bath and used. Formaldehyde (SRL Mumbai) was used as received. Dimethyl amine (Merck) acetoephone (Merck) ethyl acetate (SRL, Mumbai) were distilled before use. Double distilled water was used as solvent for the biphasic system.

Instrumentation
The FT-IR spectrum was recorded on a Perkin Elmer RX I spectrometer in the spectral region from 4400 to 400 cm\(^{-1}\) using KBr. High resolution 1H-NMR spectra and 13C-NMR spectra was recorded on a Bruker 500 MHz and Bruker DRX 125.77 MHz FT-NMR spectrometers at room temperature using D\(_2\)O solvent. Molecular weight of the polymer was determined by Waters 501 gel permeation chromatograph. Tetrahydrofuran was used as an eluent and polystyrene standards were employed for calibration. The glass transition temperature was determined with a Perkin-Elmer DSC-7 differential scanning calorimeter at a heating rate of 10ºC/min in N\(_2\) atmosphere.

Synthesis of 2-Benzoylethyldecyldimethylammonium bromide (BEDDAB)
Single site phase transfer catalyst was prepared in two stages. In the first stage dimethylaminopropiophene hydrochloride was prepared as reported in the literature [18] by treating equal moles (0.33 mole) of dry methylamine, powdered para
formaldehyde and acetophenone and 40 ml of 95% ethanol containing 0.5 ml of conc. HCl.

In the second stage 0.28 mole of the prepared dimethylaminepropiophenone hydrochloride was taken in a separating funnel and mixed with ether. Then 100 ml of sodium bicarbonate (0.1N) solution was added little by little and the separation funnel was shaken from time to time. The free amine, dimethylaminepropiophenone was extracted in ether. The ether layer containing the amine was quaternized by the addition of 0.28 mole of n-bromodecane in cold conditions. The product was allowed to stand overnight in a closed vessel and then filtered. The obtained product was purified by recrystallization using acetone-alcohol mixture. After being dried in a vacuum at 60°C for 24 hrs, the purified 2-benzoylethyldecylidimethylammonium bromide (BEDDAB) was collected. The yield in the second stage was 90%. The synthesis of BEDDAB is shown in Scheme 1

![Scheme 1. Synthesis of Benzylethyldecylidimethylammonium bromide](image)

**Polymerization Procedure**

A typical polymerization of the monomers, methyl methacrylate (MMA) and ethylmethacrylate (EMA) was carried out using a long closed Pyrex tube under unstirred, inert atmospheric conditions at 60±1°C. The reaction mixture consists of monomerin 10 ml organic phase (with conc. HCl) and the phase transfer catalyst (BEDDAB), sodium bisulphate (0.5 mole dm⁻³) for adjusting the ionic strength and sulphuric acid (0.2 mol dm⁻³) for maintaining the pH in 10 ml of aqueous phase.

Polymerization reaction was initiated by the addition of potassium peroxysulfate (PDS) to the reaction mixture. After stipulated time, the reaction was arrested by pouring the reaction mixture into ice cold methanol [5-9, 12, 13, 17]. The precipitated polymer was filtered through a sintered glass crucible, washed with double distilled water and methanol and then dried in oven (60±0.1°C) until constant weight was obtained. The rate of polymerization (Rp) was calculated using equation (1).

\[
Rp = \frac{1000 \times W}{V \times t \times M}
\]  

Where Rp - Rate of Polymerization; W - Weight of polymer in grams; V - Volume of reaction mixture; t - Reaction time in seconds; M - Molecular weight of the monomer.

**Results and Discussion**

**Synthesis of 2-Benzoylethyldecylidimethylammonium bromide (BEDDAB)**

In the first stage dimethylaminepropiophenone hydrochloride was prepared by condensing dimethylamine and acetonaphene with formaldehyde in the presence of conc. HCl at slightly warm conditions.

The dimethylaminepropiophenone hydrochloride was then neutralized by treating with sodium bicarbonate to isolate dimethylaminepropiophenone which was extracted with ether. The amine was then quaternized by the addition of n-bromodecane in cold conditions. Thus the obtained product was purified by recrystallization using acetone-alcohol mixture. After being dried in a vacuum at 60°C for 24 hrs, the purified 2-benzoylethyldecylidimethylammonium bromide was collected. The synthesis of BEDDAB is shown in Scheme 1.

**Characterization of BEDDAB**

**FT-IR spectral analysis of BEDDAB**

The FT-IR spectrum of BEDDAB is shown in Fig 1: 3401 cm⁻¹ (over tone of carbonyl group), 3068 cm⁻¹ (aromatic C-H stretching), 2987, 2965 cm⁻¹ (symmetrical, asymmetrical C-H stretching), 1720 cm⁻¹ (C=O stretching), 1597, 1508 and 1445 cm⁻¹ (C=C stretching vibrations of the ring), 1459 cm⁻¹ (C-H bending vibrations in the aromatic ring), 1377 cm⁻¹ (-CH₂-N stretching), 932 cm⁻¹ (due to rocking of-CH₂ group), 922 and 747 cm⁻¹ (C-H out of plane bending vibrations of the aromatic nuclei).

![Figure 1. FT-IR Spectrum of BEDDAB](image)

**¹H-NMR spectral analysis of BEDDAB**

¹H-NMR spectrum of BEDDAB is shown in Fig 2.
The following resonance signals were observed for BEDDAB: 7.57, 7.43 and 7.34 ppm (aromatic protons), 2.91 and 2.76 ppm (methylene groups attached to the carboxyl carbon and the nitrogen atom respectively), 2.53 ppm (methylene group of the decyl group which is attached to the nitrogen atom), 2.33 and 2.25 ppm (proton signals due to the methyl groups attached to the nitrogen atom), 0.95 ppm (methyl protons of the decyl group), 1.64 and 1.21 ppm (other methylene protons of the decyl group).

![Figure 2. ¹H-NMR Spectrum of BEDDAB](image)

**Figure 2. ¹H-NMR Spectrum of BEDDAB**

**¹C-NMR spectral analysis of BEDDAB**

¹C-NMR spectrum of BEDDAB was shown in Fig. 3. The following resonance signals were observed in the spectra: 200.62 ppm (carbonyl carbon), 136.24, 133.96, 128.96 and 128.88 ppm (aromatic carbons), 59.74 and 57.02 ppm (methylene carbons attached to the nitrogen atom), 43.04 ppm (methylene carbon attached to the carboxyl carbon), 46.91 ppm (methyl carbons attached to the nitrogen atom), 14.11 ppm (methyl carbon of the decyl group), 33.49, 30.94, 30.14, 28.31, 27.23 and 23.12 ppm (other methylene carbons of the decyl group).

![Figure 3. ¹C-NMR Spectrum of BEDDAB](image)

**Figure 3. ¹C-NMR Spectrum of BEDDAB**

**Elemental analysis of BEDDAB**

Carbon, Hydrogen and Nitrogen contents of BEDDAB has been analyzed and the results are very close to the theoretical values. Molecular Formula: C_{17}H_{38}BrNO; Mol.Wt.: 398; Elemental analysis (%): C: 63.27 (Found); 63.31 (Calculated), H: 9.13 (Found); 9.11 (Calculated), N: 3.49 (Found): 3.52 (Calculated).

**The Kinetics of Free Radical Polymerization**

The kinetics of free radical polymerization of methyl and ethyl methacrylate using BEDDAB as catalyst and PDS as initiator under ethyl acetate / water biphasic media was studied under following experimental conditions.

**Steady state rate of polymerization**

The rate of polymerization of the monomers was ascertained by keeping the concentration of monomers 2.0 mol dm⁻³ and PDS as 2.0x 10⁻³ mole dm⁻³, volume of aqueous and organic phase as 10 ml, the concentration of sulphuric acid as 0.2 mole dm⁻³, concentration of sodium bisulphate as 0.5 mole dm⁻³ and the polymerization was started by adding 1.0 x 10⁻¹ mole dm⁻³ of BEDDAB to the aqueous phase. Table 1 shows the rate of polymerization of MMA and EMA at different time intervals.

Fig. 4 shows the plot of rate of polymerization versus time intervals. The steady state rate of polymerization was arrived from the plot and it has been fixed as 50 minutes for both methyl methacrylate and ethyl methacrylate using BEDDAB as PTC.

![Figure 4. Plot of rate of polymerization vs. Time](image)
**Effect of monomer concentration on Rp**

The effect of monomer concentration on the rate of polymerization was studied by varying the concentration in the range of 0.8 to 1.8 mole dm\(^{-3}\) by keeping the concentration of PDS as 0.02 mole dm\(^{-3}\), PTC as 0.1mole dm\(^{-3}\), ionic strength as 0.5mole dm\(^{-3}\) and pH as constant. Table 2 shows the variation of in Rp with increase in concentrations of the monomers. It was found that the Rp increases with increase in the concentration of monomers.

The order of the reactions with respect to variations in concentration of monomers was determined from the slope by plotting log Rp versus log [monomer] as shown in Fig 5. The reaction orders with respect to monomer concentration for MMA and EMA were nearly half order. Also Fig 6 shows the plot of Rp versus concentration of monomer raised to suitable power passes through the origin in each case, which confirms the above observation with respect to [RMA].

**Figure 5.** Plot of log Rp vs. log[RMA]

![Figure 5](image-url)

**Figure 6.** Plot of [RMA] \(^0.5\) Vs Rp

![Figure 6](image-url)

In the case of free radical polymerization of vinyl monomers, the order with respect to monomer is found to be 1.0. The deviation from the first order [19-21] with respect to monomer may be attributed to any one of the factors such as concentration of monomer involved in the initiation step, primary radical termination and occlusion phenomenon or gel effect.

**Effect of initiator concentration on Rp**

The effect of concentration of K\(_2\)S\(_2\)O\(_8\) on the rate of polymerization of RMA were studied by varying the concentration of K\(_2\)S\(_2\)O\(_8\) in the range of 0.015 to 0.025 mole dm\(^{-3}\) by keeping the concentrations of monomer as2. 0 mole dm\(^{-3}\), catalyst as 0.1mole dm\(^{-3}\) and at constant ionic strength, pH and volume ratio of aqueous to organic phase. As the concentration of PDS was increased (Table 3), Rp was found to increase. Fig 7 shows the plot of log Rp versus log [K\(_2\)S\(_2\)O\(_8\)], the order of reaction was found to be nearly unity for MMA [22, 23] and 0.7 for EMA. Fig 8 and Fig 9 show that the plot of Rp versus [K\(_2\)S\(_2\)O\(_8\)] for MMA and EMA is linear and the line passed through the origin which confirms above observation. In the case of free radical polymerization of vinyl monomers, the order with respect to initiator is found to be square root of initiator concentration when the polymer radical terminates by mutual bimolecular reaction.

**Table 3.** Dependence of Rp on [K\(_2\)S\(_2\)O\(_8\)] in RMA-BEDDAB-K\(_2\)S\(_2\)O\(_8\) [Monomer]= 2.0 mol dm\(^{-3}\); [BEDDAB] =1.0 x 10\(^{-5}\) mol dm\(^{-3}\); [H\(_2\)SO\(_4\)] = 0.2 mol dm\(^{-3}\); [NaHSO\(_3\)] = 0.5 mol dm\(^{-3}\);

The higher order of polymerization in the case of MMA may be either due to the induced decomposition of the initiator or due to the decrease in termination rate constant [24].

![Figure 7](image1.png)

Figure 7. Plot of log Rp vs. log [PDS]

![Figure 8](image2.png)

Figure 8. Plot of [PDS] Vs Rp for MMA

![Figure 9](image3.png)

Figure 9. Plot of [PDS] Vs Rp for EMA

The induced decomposition of peroxysulphate in the presence of oxidizable organic compounds is well known. The decomposition of PDS in water was greatly enhanced [25, 26] in the presence of methanol, ethanol, ethyl acetate etc. The SO₄⁻ ion generated in the primary decomposition event attacks the organic compounds absorbing sulfate from it forming HSO₄⁻ and carbon centered free radicals such as CH₃OH in the case of methanol and CH₃COO'CH₃ and CH₂COOCH₂CH₂ in case of ethyl acetate.

**Effect of concentration of BEDDAB on Rp**

At fixed concentration of other parameters, the effect of [BEDDAB] on Rp was determined by varying its concentration in the range of 0.015-0.025 mole dm⁻³. Table 4 shows that Rp increased with increase in concentration initially but there observed a slight decrease in Rp at higher concentration.

**Table 4.** Dependence of Rp on [PTC] in RMA-BEDDAB-K₂S₂O₈ [Monomer] = 2.0 mol dm⁻³ [PDS] = 2.0 x 10⁻³ mol dm⁻³ [H₂SO₄] = 0.2 mol dm⁻³ [NaHSO₃] = 0.5 mol dm⁻³

A leveling off tendency was shown at higher concentration. Thesame leveling off tendency was also reported [27, 28] when the concentration of PTC reached maximum in the radical polymerization of alkyl methacrylates using potassium peroxomonosulphate as initiator.

Fig 10 shows the order with respect to the concentration of the catalyst which was found to be around 0.5 from the plot of log Rp versus log [PTC]. The plot of Rp versus [PTC]⁻¹ was found to be linear passing through the origin confirming the above results which is shown in Fig 11. In the absence of PTC it has been observed that there was no polymerization reaction even after several hours.

In the present case a slight decrease in rate of polymerization which is observed as the concentration reached maximum may be attributed to steric hindrance of bulky benzyl group in the catalyst. This bulky group would have hampered the effective transfer of anion to the organic phase at higher concentrations. At higher concentration of the catalyst there will be interaction of the positively charged carbonyl carbon and the negatively charged oxygen atom with anion and cation of another catalyst molecule and this may also offer steric resistance for the transfer of anion to the growing chain. Therefore the rate does not increase beyond a limit due to which leveling off tendency is observed.
**Effect of variation of temperature on Rp**

The influence of temperature in the range 50 to 65°C on the rate of polymerization was studied at fixed concentration of monomer, initiator, catalyst, acid strength and ionic strength. Rp increased with increase in temperature as shown in Table 5. The activation energy for the overall rate of polymerization has been calculated from the slope of Arrhenius plot of log Rpverses 1/T as shown in Fig 12, based on the value of activation energy, the other thermodynamic parameters were computed in Table 6.

<p>| Table 5. Effect of Temperature on Rp in RMA-BEDDAB-K$_2$S$_2$O$_8$ [Monomer]= 2.0 mol dm$^{-3}$;[BEDDAB] =1.0 x 10$^{-4}$mol dm$^{-3}$;[H$_2$SO$_4$] =0.2 mol dm$^{-3}$;[NaHSO$_3$] =0.5 mol dm$^{-3}$; [PDS] = 2.0 x 10$^{-4}$mol dm$^{-3}$; |

**Figure 10.** Effect of [PTC] on Rp

**Figure 11.** Plot of [PTC]$^{0.5}$ VsRp

The value of activation energy for the polymerization of methyl methacrylate is lower than that of ethyl methacrylate which is evident from the higher rate of polymerization of methyl methacrylate than that of ethyl methacrylate.

**Product Analysis**

The FT-IR spectra of the products obtained by phase transfer polymerization of MMA and EMA show the disappearance of the peak at 1635 cm$^{-1}$ which is originally present in the FT-IR spectrum of the monomers which suggests that the olefinic double bond is involved in the polymerization and the product is polymethyl methacrylate and ethyl methacrylate respectively.

The DSC curve of the product obtained from MMA shows an endotherm due the glass transition of poly (MMA) and the Tg value was found to be 106°C. The value is comparable to the literature value for crystalline poly (MMA) (105°C). The DSC curve of the product obtained from EMA shows an endotherm due the glass transition of poly (EMA) and the Tg value was found to be 65°C. The Tg value of the polymer depends on tacticity and molecular weight.

**Determination of Molecular Weight of Polyalkylmethacrylates**

The molecular weight of polymers has been established by GPC technique. The number average molecular weight (Mn), weight average molecular weight (Mw) and the polydispersityindex(Mw/Mn) values are shown in Table 7. The molecular weight of polymer which has been synthesized by using BEDDAB at low concentration of monomer and fixed concentrations of initiator and PTC are denoted as poly(alkyl methacrylate-L) and those synthesized at higher concentration of monomer and fixed concentrations of initiator and PTC are denoted as poly(alkyl methacrylate-H).
The poly index values of both poly methyl methacrylate and poly ethyl methacrylate suggest that the chain termination takes place predominantly by disproportionation [29, 30]. The Molecular weight of poly methyl methacrylate formed is found to be greater than that of poly ethyl methacrylate. As the rate of polymerization of methyl methacrylate is found to be greater than that of ethyl methacrylate this trend may be observed which is attributed to the difficulty in the chain propagation in the polymerization of ethyl methacrylate than methyl methacrylate. Molecular weight of the polymers increased as the concentration of the monomers increased.

### Kinetic Scheme and Mechanism

Scheme 2 represents the kinetic investigation of the polymerization of alkylmethacrylates(M) initiated by K$_2$S$_2$O$_8$/PTC in ethyl acetate / water biphasic system. The subscripts (w) and (o) represent aqueous and organic phases. $k_i$, $k_p$ and $k_t$ refer to the rate of initiation, rate of propagation and rate of termination and Q represent phase transfer catalyst.  

**Phase transfer**  
$$2Q^{+} + S_2O_8^{2-} \xrightarrow{k_p} (Q^{+})_2 (S_2O_8^{2-})_w$$  
$$Q^{+} + S_2O_8^{2-} \xrightarrow{k_t} 2Q^{+}S_2O_8^{2-}$$  

**InitiationPropagation**  
$$M_1^i + M \xrightarrow{k_p} M_2^i$$  

**Termination**  
$$2M_n^i + k_t \xrightarrow{} Polymer$$  

Based on the mechanism the rate of polymerization for RMA catalyzed using BEDDAB has been derived as  
$$R_P = k_p \left( \frac{[M]}{[Q^+]_{ext}} \right)^{1/2} \left[ M_2 \left[ S_2 O_8^{2-} \right] \right]^{1/2} \left[ Q^+ \right]_{total}$$  

The above equation satisfactorily explains all the experimental results and observations. The increase in Rp with increase in [PTC] and [K$_2$S$_2$O$_8$] may be due to anincrease in the amount of $Q_2S_8$O$_8$ transferred to the organic phase, which in turn increase the number of SO$_4^-$radical ions.

### Conclusion

A new single site phase transfer catalyst, 2-benzoylethyldecyldimethylammonium bromide was prepared and characterized using spectroscopic techniques. The kinetics of free radical polymerization of alkyl methacrylate initiated by K$_2$S$_2$O$_8$ was studied using newly synthesized single site PTC in ethylacetate / water biphasic media under inert condition. Rate of polymerization was evaluated at different concentration of monomer, initiator, PTC and temperature. The order with respect to monomer was found to be 0.5 and around unity with respect to initiator, half order with respect to single site PTC. Based on the results obtained a suitable kinetic mechanism has been proposed. Molecularweight of PMMA was found to be high at higher concentration of monomer and at fixed concentrations of initiator and PTC. The formation of polymers was confirmed by FT-IR analysis.
